

Objective: Create a Linux health monitoring script that reports key system metrics, such as disk space, memory usage, CPU load, running processes, and network connectivity. This will provide a real-time snapshot of the system's health. Follow the instructions below to complete the assignment and submit a detailed report, including screenshots of your implementation

Implementation: Created a replica of 'Neofetch' a popular package used to obtain information of *NIX (Linux, MacOS, FreeBSD etc.) systems.

Screenshots:

Output:

```

root@13NSY1:~/202
root@13NSY1:~# mkdir 202
root@13NSY1:~# cd 202
root@13NSY1:~/202# touch script.sh && vim script.sh
root@13NSY1:~/202# vim script.sh
root@13NSY1:~/202# chmod +x script.sh
root@13NSY1:~/202# ./script.sh
root@13NSY1
-----
OS: Ubuntu 24.04.1 LTS
Kernel: 5.15.153.1-microsoft-standard-WSL2
Shell: /bin/bash
Uptime: 2 hours, 59 minutes
CPU Load Avg: 0.00, 0.00, 0.00
CPU: AMD Ryzen 5 PRO 2500U (2)
GPU: Microsoft Corporation Basic Render Driver
Memory: 690Mi / 3.8Gi
root@13NSY1:~/202# neofetch
root@13NSY1
-----
OS: Ubuntu 24.04.1 LTS on Windows 10 x86_64
Kernel: 5.15.153.1-microsoft-standard-WSL2
Uptime: 2 hours, 59 mins
Packages: 1044 (dpkg), 9 (snap)
Shell: bash 5.2.21
Theme: Adwaita [GTK3]
Icons: Adwaita [GTK3]
Terminal: Relay(468)
CPU: AMD Ryzen 5 PRO 2500U w/ Radeon Vega Mobile Gfx (2) @ 1.996GHz
GPU: e824:00:00:00 Microsoft Corporation Basic Render Driver
Memory: 487MiB / 3921MiB

```

The above picture shows implementation of my script followed by Neofetch's output.

Line by line:

1. Make a directory named "202" in the current directory.
2. Change directory to 202
3. Create script.sh file and open it in Vim editor

```
root@13N5Y1:~/202# lsb_release -d
No LSB modules are available.
Description:      Ubuntu 24.04.1 LTS
```

The image shows regular output of `lsb_release -d`. The tab(`\t`) is between Description: and Ubuntu, `awk -F '\t'` separates the everything before and after the tab and `{print $2}` selects the second part (Ubuntu...)

`uname -r`: prints kernel release information.

`$SHELL`: The environment variable that stores shell's absolute path (`/bin/zsh`).

`uptime -p`: Prints how long device has been up and running.

`sed`: Used for editing strings. In this case it searches for every instance of 'up' (`s/ up`), and replaces it with an empty string (`//`).

```
root@13N5Y1:~/202# uptime -p
up 3 hours, 46 minutes
```

Default output of `uptime -p`.

`Awk -F "load average: "` splits the output of `uptime` into two parts. One before (and including) load average and the other everything after it. `{print $2}` prints the second part of the spliced string.

`lscpu`: prints CPU information.

`grep`: Finds select string from output.

`lspci`: List PCI devices (network card, GPU) information.

`memory_info`: user defined variable.

`if`: if statement to give output if certain conditions are met

`bc`: inbuilt calculator tool to calculate if memory usage is greater than 90 percent

`else`: else condition if true condition is false

`fi`: end if statement

```
nc -z 1.1.1.1 53 > /null 2>&1 && echo -e "\e[1;32mInternet ON\e[0m" || echo "\e[1;31mDevice not connected to internet\e[0m"
```

Added this to the end of the script to check network connection using netcat to scan for open ports on Cloudflare's DNS server. `-z` option does not send any data. It follows by sending the standard output and error of `nc` to `/null` (should've been `/dev/null` according to standards) so it does not print in terminal.
